Abstract

*A hybrid (non-ray, non-modal) method for computing the fields of a paraxial beam propagating in a multimode waveguide (parallel-plate or dielectric slab) at large axial distances is presented. The method is based on the Fourier and Fresnel self-imaging properties of these waveguides, and is capable of high accuracy. The method is much more efficient than ray or mode approaches, while giving complete field information which coupled-power equations do not provide.*

Acknowledgments

The authors are indebted to Prof. R. MacRae for a useful discussion about theta-functions and Gaussian sums. Numerical work for this paper was prepared by Mr. S. Nakayama and Ms. R. Ebrahimian. This work was carried out under the support of the U.S. Army Research Office (ARO), grant. no. DAAG 29-G-0173, Dr. J. Mink, project monitor.

## I. INTRODUCTION

Multimode optical fibers appear at present to be the most common optical waveguiding medium for applications in the immediate future. Incoherent sources and relatively simple detectors can be used, and the tolerance problems encountered with single-mode fibers are far less severe with such waveguides.

At present, there are essentially three methods available for field computation in multimode waveguides. First, one can take a pure modal approach--the excitation amplitude of each mode is computed, and all modes are summed together. Although in principle exact, this approach suffers not only from the large number of modes which must be kept track of (100~1000 for a typical fiber; 30~100 for a slab geometry) but also from a large degree of cancellation of terms in the mode sum when the field does not match that of an individual mode. Examples of the application of this method may be found in [1]. Although in some special cases approximate closed-form results are available, a computer analysis is generally required, and roundoff errors can be expected to accumulate, especially for large propagation distances.

A second approach is that of geometrical optics (sometimes encountered as the WKB method). An excellent discussion of this approach has been given by Gloge and Marcatili [2] (see also [3]). Here one approximates the effect of a large number of discrete propagating modes by a continuously distributed propagation constant belonging to a "continuous spectrum" of modes. These, when computed under the WKB approximation, can be interpreted as a cone of rays lying within some characteristic acceptance

angle of the fiber. The propagation problem then reduces to that of determining the amplitude with which each ray is excited, and tracing it down the length of the guide. Intuitively more suitable for multimode guides because of the "high-frequency" nature of the problem, this approach is nonetheless approximate by virtue of the geometrical optics technique. Moreover, in a situation where paraxial propagation conditions exist (see below), a large number of rays can be expected to contribute at large propagation distances (hundreds of meters or several kilometers may not be uncommon). In this region, the geometrical optics approach can be seen to suffer from similar disadvantages as does the first.

A third approach (see, e.g., [4],[5],[39]) is a purely numerical one, wherein the partial differential equation--Helmholtz or its parabolic approximant--is tackled directly, without the use of either mode or ray concepts. In [4] and [5], the equation is discretized and solved with the aid of fast Fourier transform techniques. This method, like the first, is also capable of arbitrary accuracy in principle, and requires neither a detailed knowledge of a large number of modes, nor the tracing of a large number of ray paths. Again, however, when very long propagation distances are being studied, the discretization of the wave equation in the longitudinal direction can lead to large error accumulations which do not seem easily avoidable by this technique.

Finally, we might also mention here the coupled-power equations approach [1]. This method seeks only to find the total power carried by each mode, since for many applications the details of the field distribution from each mode are not of interest. One then takes a statistical approach to these equations, and obtains useful results for pulse dispersion

when each mode of the guide is detectable only through its total power. There are many other applications, however, when the fields themselves are important, such as in the design of couplers, splitters, switches, splicers, etc., and it is this problem in which we are interested here.

The method we propose is based on the imaging properties of multi-mode waveguides. In the paraxial approximation, a parallel-plate or dielectric slab waveguide will periodically reconstruct the field pattern at the input plane (and, at more frequent intervals, a string of such replicas). Because of this, we need only perform our field computations within the space of one of these periods, and will not suffer the loss of accuracy at large distances associated with the methods described above. Our computations will be performed for a parallel-plate waveguide with perfectly conducting walls, but the results are immediately applicable to the dielectric slab waveguide (Appendix A). The method will allow a simple formula to be obtained for the propagation of a Gaussian beam of substantially narrower width than that of the guide. (Note that the study by Felsen and Shin [6] of beam propagation in waveguides is in practice restricted to beams which propagate obliquely to the axis of the guide, and actually will suffer from the same drawbacks at large axial distances as does the ray method, although it is probably superior to the ray method at shorter distances). Numerical comparisons with exact (modal) calculations are quite favorable, even for rather large propagation distances.

## II. THE PARAXIAL APPROXIMATION

To fix ideas, let us consider the parallel-plate waveguide illustrated in Fig. 1 (the discussion of this section, however, is quite general and need not be restricted to this specific waveguide). The walls at  $x = 0$  and  $x = a$  are perfectly conducting, and some known source produces a given excitation or input field at the plane  $z = 0$ . For simplicity, we restrict ourselves to two dimensional, TE fields, so that the entire field  $\vec{H} = \bar{a}_x H_x + \bar{a}_z H_z$ ,  $\vec{E} = \bar{a}_y E_y$ , where  $\bar{a}_x, \bar{a}_y, \bar{a}_z$  are Cartesian unit vectors, can be derived from the scalar function  $E_y$  which satisfies

$$\left( \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial z^2} + k^2 \right) E_y = 0 \quad (1)$$

for  $z > 0$ . Here  $k = \omega\sqrt{\mu\epsilon}$ , where a time dependence  $\exp(i\omega t)$  has been assumed, and  $\mu, \epsilon$  are the electrical parameters of the medium filling the waveguide.

In the paraxial approximation, we write

$$E_y(x, z) = e^{-ikz} A(x, z) \quad (2)$$

and assume that most propagation takes place nearly in the  $z$ -direction; that is,  $A(x, z)$  as a function of  $z$  varies slowly compared to  $\exp(-ikz)$ . Inserting (2) into (1) we obtain

$$\left( \frac{\partial^2}{\partial x^2} - 2ik \frac{\partial}{\partial z} + \frac{\partial^2}{\partial z^2} \right) A(x, z) = 0 \quad (3)$$

and in the paraxial approximation, we neglect the  $\partial^2/\partial z^2$  term compared to the first derivative term because of the slow variation of  $A(x, z)$  in  $z$  assumed above. We thus obtain the following parabolic equation for  $A(x, z)$ [7]:

$$\left( \frac{\partial^2}{\partial x^2} - 2ik \frac{\partial}{\partial z} \right) A(x,z) = 0 \quad (4)$$

To put this approximation on a more quantitative footing, we can apply some ideas from the boundary-layer technique [8]. By "stretching" the variable  $x$  into a new variable  $v = x/a$ , we can deal with a transverse variable  $v$  which is  $O(1)$  over the entire cross-section of the guide. When rewritten in terms of  $v$ , equation (4) becomes

$$\left( \frac{\partial^2}{\partial v^2} - 2ika^2 \frac{\partial}{\partial z} \right) A(v,z) = 0 \quad (5)$$

which suggests that the scaling  $\zeta = \text{const } z/ka^2$  might be convenient. For reasons which will become clear in the next section, we choose  $\zeta = \pi z/4ka^2$ . Making both changes of variable in (3), we have

$$\left( \frac{\partial^2}{\partial v^2} - \frac{\pi i}{2} \frac{\partial}{\partial \zeta} \right) A(v,\zeta) = - \frac{\pi^2}{16k^2 a^2} \frac{\partial^2 A(v,\zeta)}{\partial \zeta^2} \quad (6)$$

It is natural now to assume a solution to (6) of the form

$$A(v,\zeta) \sim A_0(v,\zeta) + \frac{1}{k^2 a^2} A_1(v,\zeta) + \frac{1}{k^4 a^4} A_2(v,\zeta) + \dots \quad (7)$$

so that, by matching powers of  $(ka)^{-2}$ , we find a recurrent set of equations for  $A_0, A_1$ , etc.:

$$\left( \frac{\partial^2}{\partial v^2} - \frac{\pi i}{2} \frac{\partial}{\partial \zeta} \right) A_0(v,\zeta) = 0 \quad (8)$$

$$\left( \frac{\partial^2}{\partial v^2} - \frac{\pi i}{2} \frac{\partial}{\partial \zeta} \right) A_1(v,\zeta) = - \frac{\pi^2}{16} \frac{\partial^2 A_0(v,\zeta)}{\partial \zeta^2} \quad (9)$$

and so on. As initial conditions at  $\zeta = 0$ , we require  $A_0(x/a,0) = E_y(x,0)$ -- a given function--while  $A_1(v,0) = A_2(v,0) = \dots = 0$ .

We are now in a position to estimate the magnitude of the correction term  $A_1$ , and therefore the error involved in the paraxial approximation. It is easily verified that, for example,

$$A_1(v, \zeta) = \frac{i\zeta}{2\pi} \frac{\partial^4 A_0(v, \zeta)}{\partial v^4} = -\frac{i\pi\zeta}{8} \frac{\partial^2 A_0(v, \zeta)}{\partial \zeta^2} \quad (10)$$

with  $A_2, A_3$ , etc., given by similar expressions. Because of the scaling of the variables  $v$  and  $\zeta$ , the differentiations in (10) do not increase the order of magnitude of the function  $A_0$ . Thus if  $A_0$  is  $O(1)$ , then

$$|A_1(v, \zeta)| \lesssim O(\zeta) \quad (11)$$

so a criterion for the accuracy of the paraxial approximation ( $A \approx A_0$ ) is that  $\zeta/k^2 a^2 \ll 1$ , or in other words,

$$kz \ll (ka)^4 \quad (12)$$

In addition, of course, we also have the condition  $k^2 a^2 \gg 1$ , which is implicit in the expansion (7) and the fact that the guide is highly multi-mode.

These arguments are not restricted to the case of a parallel-plate waveguide. However, as with any "order-of-magnitude" arguments, they say nothing about the proportionality constant implicit in (11). In fact, this constant will depend sensitively on the function  $A_0(v, \zeta)$ , mostly through its initial value  $A_0(v, 0)$ . Thus, a detailed study of the estimate (11) should be made when using the paraxial approximation in any specific situation. This procedure is discussed in some detail by Tappert [9], who also gives a large number of references to its use in acoustics. In Appendix A, we consider the paraxial approximation for

a dielectric slab waveguide, and demonstrate an approximate equivalence with a parallel-plate waveguide.

In closing, we might also note that Polyanskii [11] has obtained a formula relating the solution of the parabolic equation to that of the Helmholtz equation which is an alternative to the perturbation series (7). This same question is addressed from a rather different viewpoint in [36]. Further, another variant of the parabolic equation more suitable for off-axis propagation has been proposed in [12].

### III. GREEN'S FUNCTION AND IMAGING

By well-known techniques, the field  $E_y(x,z)$  for  $z > 0$  in the waveguide can be expressed in terms of the field  $E_y(x,0)$  at an input plane ( $z=0$ ) by means of a Green's function  $G(x,x';z)$ :

$$E_y(x,z) = \int_0^a E_y(x',0)G(x,x';z)dx' \quad (13)$$

where  $G$  can be expressed as a modal expansion:

$$G(x,x';z) = \frac{2}{a} \sum_{m=1}^{\infty} \sin \frac{m\pi x}{a} \sin \frac{m\pi x'}{a} e^{-i\beta_m z}; z \geq 0 \quad (14)$$

where  $\beta_m = (k^2 - m^2\pi^2/a^2)^{\frac{1}{2}}$ . On the other hand, the Green's function  $G_0$  for the paraxial approximation (2), (4) to  $E_y$  is given by:

$$G_0(x,x';z) = \frac{2}{a} e^{-ikz} \sum_{m=1}^{\infty} \sin \frac{m\pi x}{a} \sin \frac{m\pi x'}{a} e^{izm^2\pi^2/2ka^2} \quad (15)$$

Evidently  $G_0$  could have been obtained from  $G$  by replacing  $\beta_m$  by the first two terms of its binomial expansion  $\beta_m \approx k - m^2\pi^2/2ka^2$ . We see that whereas  $G$  has a large but finite number of modes which propagate, the paraxial approximation  $G_0$  has infinitely many such modes. It is convenient to rewrite  $G_0$  by expressing the sine functions as exponentials; the result is:

$$G_0(x,x';z) = \frac{1}{2a} e^{-ikz} \sum_{m=-\infty}^{\infty} e^{izm^2\pi^2/2ka^2} \left\{ e^{-im\pi(x-x')/a} - e^{-im\pi(x+x')/a} \right\} \quad (16)$$

If we define

$$z_{11} = 4ka^2/\pi \quad (17)$$

(so that the stretched variable of the previous section is  $\zeta = z/z_{11}$ ), then

$$G_0(x, x'; z) = \frac{1}{2a} e^{-ikz} \sum_{m=-\infty}^{\infty} e^{2\pi i m^2 z / z_{11}} \left\{ e^{-im\pi(x-x')/a} - e^{-im\pi(x+x')/a} \right\} \quad (18)$$

Equation (18) is the basis for the so-called Fourier-and Fresnel-imaging properties of this waveguide [13]. It is easily seen from (18) that  $\exp(ikz)G_0$  is a periodic function of  $z$ :

$$G_0(x, x'; z + z_{11}) = G_0(x, x'; z) e^{-ikz_{11}} \quad (19)$$

In particular, since (13) implies that  $G(x, x'; 0)$  is equal to  $\delta(x-x')$  for  $0 \leq (x, x') \leq a$ , we have

$$G_0(x, x'; nz_{11}) = \delta(x-x') e^{-iknz_{11}} \quad (20)$$

for any integer  $n$ , i.e., the input plane field is replicated at each of the Fourier image planes  $z = nz_{11}$ . This phenomenon was first investigated theoretically for unbounded periodic gratings, and the imaging distance was first given by Rayleigh [14]. Later treatments have been given in [13], [15]-[17]. Because of the mathematical equivalence of a waveguide with a periodic system, this imaging also occurs in waveguides--a fact apparently first noticed by Rivlin and Shul'dyaev [18] and discussed at length by a number of authors [10],[19]-[23],[37].

An even more interesting occurrence shows up at  $z = z_{pq}$ , where

$$z_{pq} = \frac{q}{p} z_{11} \quad (21)$$

and  $p$  and  $q$  are some positive integers. Let us consider the sum

$$Q_{pq}(x) = \sum_{m=-\infty}^{\infty} e^{-im\pi x/a + 2\pi i m^2 z_{pq}/z_{11}} \quad (22)$$

Let  $m = p\ell + r$ , where  $r$  runs from 0 to  $p-1$ , and express (22) as a double sum:

$$\begin{aligned} Q_{pq}(x) &= \sum_{\ell=-\infty}^{\infty} \sum_{r=0}^{p-1} e^{-i\pi x(p\ell+r)/a + 2\pi i q [p\ell^2 + 2\ell r + r^2/p]} \\ &= \sum_{r=0}^{p-1} e^{-i\pi r x/a + 2\pi i q r^2/p} \left( \sum_{\ell=-\infty}^{\infty} e^{-i\pi p\ell x/a} \right) \end{aligned} \quad (23)$$

However, the summation in parenthesis is nothing more than  $Q_{11}(px)$ , although now the argument can range not just from  $-a$  to  $+a$  (or 0 to  $2a$ ), but from  $-pa$  to  $+pa$  (or 0 to  $2pa$ ). Making use of the formula [24]:

$$\sum_{m=-\infty}^{\infty} e^{2\pi i m x/d} = d \sum_{n=-\infty}^{\infty} \delta(x - nd) \quad (24)$$

for any positive  $d$ ,

$$Q_{pq}(x) = \frac{2a}{p} \sum_{r=0}^{p-1} e^{-i\pi r x/a + 2\pi i q r^2/p} \sum_{n=-\infty}^{\infty} \delta\left(x - \frac{2na}{p}\right) \quad (25)$$

From (18), then, we have

$$G_0(x, x'; z_{pq}) = e^{-ikz_{pq}} \sum_{n=-\infty}^{\infty} c_n(p, q) \left[ \delta\left(x - x' - \frac{2na}{p}\right) - \delta\left(x + x' - \frac{2na}{p}\right) \right] \quad (26)$$

where the coefficients  $c_n$  are given by

$$c_n(p, q) = \frac{1}{p} \sum_{r=0}^{p-1} e^{2\pi i r(rq+n)/p} \quad (27)$$

These coefficients are known as Gaussian sums, and play a key role in analytic number theory [25]. Their most important properties are summarized in Appendix B.

For  $p = 1$ , only one of the delta-functions,  $\delta(x-x')$ , is nonzero in the range  $0 \leq (x, x') \leq a$ , and we recover the single Fourier image described before. If  $p > 1$  on the other hand, more of the delta-functions in (26) may appear in this range. Each one contributes to (13) a replica of the input field which is shifted by some amount in the  $x$ -direction,

and whose amplitude is  $|c_n(p,q)|$  times that of the original image. Any terms arising from the terms  $\delta(x+x^b - 2na/p)$  are inverted as well. Images of this type have been called Fresnel images.

For an input function not symmetric with respect to the center of the guide  $x = a/2$ , we have depicted the various images along with their (complex) amplitudes in Fig. 2 for  $z_{21}$ ,  $z_{31}$  and  $z_{41}$ . The phase factor  $\exp(-ikz)$  is omitted in this figure. Figure 2(a) illustrates the input function  $E_y(x,0)$ . At  $z = z_{21}$ , there is only one image, which is inverted with respect to the original, but is also a further  $180^\circ$  out of phase with respect to the input after the factor  $\exp(-ikz)$  is accounted for (Fig. 2(b)). At  $z = z_{31}$  (Fig. 2(c)), the situation is more involved. One of the images is an unchanged replica, reduced in amplitude by  $1/\sqrt{3}$  and phase shifted by  $90^\circ$ . The other two image terms have "broken up" and rearranged the original pattern. Between them, they both contain two complete replicas of the original, and again the amplitude of each is reduced by  $1/\sqrt{3}$ . Note that this amplitude reduction is consistent with the fact that all of the power of the original pattern must be divided between the three split images. At  $z = z_{41}$ , there is both an erect and an inverted image (Fig. 2(d)).

For the special case of a symmetric excitation,  $E_y(x,0) = E_y(a-x,0)$ ,  $z_{21}$ ,  $z_{41}$  and indeed  $z_{81}$  all reproduce the original input function (Fig.3(a)). If the input function is a beam of sufficiently narrow width, we can recognize three essentially distinct images at  $z_{31}$  (Fig. 3(b)). At other image planes, similar conclusions hold.

The Fourier and Fresnel images allow us, in principle, to compute the field in the waveguide at any point  $z_{pq}$  (and any arbitrary value of  $z$  can be approached as nearly as desired by such a point). This

procedure could, however, require a large value of  $p$ , and hence an inordinately large number of image terms, resulting in a method which is no more efficient than the modal approach. In the next section, we will show how, for a certain specific type of excitation, efficient field computation can be carried out for any value of  $z$ , using only a relatively small number of images.

Let us emphasize in closing this section that the imaging phenomenon results from the collective interference of the mode sum (14), or alternatively from the interference of the series of "rays" (plane waves) represented by (18), depending on one's preferred physical picture. The only assumption involved is the paraxial approximation, and in the case of the parallel-plate waveguide, no approximation of the mode functions themselves is needed. In the case of a dielectric waveguide, some small higher-order corrections to the mode functions will be needed (see Appendix A).

## IV. PROPAGATION OF A GAUSSIAN BEAM

Consider the initial field distribution

$$E_y(x,0) = e^{-\frac{(x-x_0)^2}{2w_0^2}} \quad (28)$$

i.e., a Gaussian beam centered at  $x_0$  with waist parameter  $w_0$ .

Let  $0 < x_0 < a$ , and assume that the "tails" of the beam are negligible at the walls of the guide:

$$w_0 \ll x_0 ; \quad w_0 \ll a - x_0$$

In addition, we also suppose that the beam is well collimated,  $kw_0 \gg 1$ .

Under these conditions and the paraxial approximation, (13) can be replaced by

$$E_y(x,z) = \int_{-\infty}^{\infty} e^{-\frac{(x'-x_0)^2}{2w_0^2}} G_0(x,x';z) dx' \quad (29)$$

We wish to evaluate (29) for arbitrary (not necessarily rational) values of  $z/z_{11}$ .

To do this it is convenient to express  $G_0$  in terms of the Jacobian theta-function  $\vartheta_3$ , defined by Whittaker and Watson [26] as:

$$\vartheta_3(z|\tau) = \sum_{m=-\infty}^{\infty} e^{m^2\pi i\tau + 2miz} \quad (30)$$

(the argument  $z$  is conventionally used in this connection and should not be confused with the cartesian coordinate  $z$  used above). This function has a wealth of useful properties which we summarize in Appendix B. The theta-function appears in solutions of other parabolic equations, such as the heat equation [27]. In the paraxial parabolic equation, however, the arguments  $z$  and  $\tau$  are both real (see below) and  $\vartheta_3$  must be treated as a generalized function.

Using (30),  $G_0$  becomes

$$G_0(x, x'; z) = \frac{1}{2a} e^{-ikz} \left\{ \mathcal{J}_3 \left( \frac{\pi(x-x')}{2a} \middle| \frac{2z}{z_{11}} \right) - \mathcal{J}_3 \left( \frac{\pi(x+x')}{2a} \middle| \frac{2z}{z_{11}} \right) \right\} \quad (31)$$

From (29), then

$$E_y(x, z) = \frac{e^{-ikz}}{2a} \int_{-\infty}^{\infty} e^{-(x'-x_0)^2/2w_0^2} \left[ \mathcal{J}_3 \left( \frac{\pi(x-x')}{2a} \middle| \frac{2z}{z_{11}} \right) - \mathcal{J}_3 \left( \frac{\pi(x+x')}{2a} \middle| \frac{2z}{z_{11}} \right) \right] dx' \quad (32)$$

With the help of (B.11) we obtain

$$E_y(x, z) = \frac{w_0}{a} \sqrt{\frac{\pi}{2}} e^{-ikz} \left\{ \mathcal{J}_3 \left( \frac{\pi(x-x_0)}{2a} \middle| \frac{2z}{z_{11}} + \frac{i\pi w_0^2}{2a^2} \right) - \mathcal{J}_3 \left( \frac{\pi(x+x_0)}{2a} \middle| \frac{2z}{z_{11}} + \frac{i\pi w_0^2}{2a^2} \right) \right\} \quad (33)$$

Note that eqn. (33) differs from the paraxial Green's function  $G_0(x, x'; z)$  in eqn. (31) only in that the source point  $(x', 0)$  has been changed to the complex location  $(x_0, -ikw_0^2)$ , and in the presence of a normalizing factor  $w_0 \sqrt{2\pi} \exp(-k^2 w_0^2)$ . The beam field in (33) is thus the equivalent of the field of a source at a complex position, as has been noted previously [6], [28], [29].

Let us first consider the focussing relative to  $z_{11}$ . Let

$z = qz_{11} + \Delta z$ , where  $-z_{11}/2 \leq \Delta z \leq z_{11}/2$  and  $q$  is an integer. From

(B.3) and (B.8), we have

$$E_y(x, z) = \frac{w_0}{f(\Delta z)} e^{-ikz} \left\{ e^{-(x-x_0)^2/2f^2(\Delta z)} \mathcal{J}_3 \left( \frac{ia(x-x_0)}{f^2(\Delta z)} \middle| \frac{2ia^2}{\pi f^2(\Delta z)} \right) - e^{-(x+x_0)^2/2f^2(\Delta z)} \mathcal{J}_3 \left( \frac{ia(x+x_0)}{f^2(\Delta z)} \middle| \frac{2ia^2}{\pi f^2(\Delta z)} \right) \right\} \quad (34)$$

where we have defined a "complex waist parameter"  $f(\Delta z)$  as

$$f^2(\Delta z) = w_0^2 \left[ 1 - i \frac{4a^2}{\pi w_0^2} \frac{\Delta z}{z_{11}} \right] = w_0^2 - i\Delta z/k \quad (35)$$

Using (B.12), we can further reduce (34) to

$$E_y(x, z) = \frac{w_0}{f(\Delta z)} e^{-ikz} \sum_{m=-\infty}^{\infty} \left\{ e^{-(x-x_0+2ma)^2/2f^2(\Delta z)} - e^{-(x+x_0+2ma)^2/2f^2(\Delta z)} \right\} \quad (36)$$

Now

$$\frac{1}{2f^2(\Delta z)} = \frac{1}{2w^2(\Delta z)} + \frac{i\Delta z/kw_0^2}{2w^2(\Delta z)} \quad (37)$$

where the waist size  $w(\Delta z)$  is given by

$$w^2(\Delta z) = w_0^2 + (\Delta z/kw_0)^2 \quad (38)$$

so we can see that (36) represents an infinite series of Gaussian beams, each broadened from its focal plane  $z = z_{11}$  as if it were propagating in free space. We illustrate this in Fig. 4. As  $\Delta z$  increases, more and more of the "image" beams contribute significantly to the field in  $0 \leq x \leq a$ . At  $\Delta z = z_{11}/2$  (say), the waist size has become

$$w^2(z_{11}/2) = w_0^2 + (2a^2/\pi w_0)^2 \approx 4a^4/\pi^2 w_0^2 \gg a^2$$

because our assumptions about the beam imply  $a \gg w_0$ . Thus we may require quite a few terms of the image series (36) in order to compute the fields at certain values of  $z$ .

For such values of  $\Delta z$ , we seek to improve the efficiency of our scheme by transforming (33) in a somewhat different manner. Applying relation (B.9), we find that

$$E_y(x, z) = \frac{w_0}{a} \sqrt{\frac{\pi}{2}} e^{-ikz} \sum_{r=0}^{p-1} e^{\pi i r^2 2z/z_{11} - \pi^2 r^2 w_0^2/2a^2} \cdot \left\{ e^{i\pi r(x-x_0)/a} \mathcal{J}_3 \left( p \left[ \frac{\pi(x-x_0)}{2a} + \frac{2\pi r z}{z_{11}} + i r \frac{\pi w_0^2}{2a^2} \right] \middle| p^2 \frac{2z}{z_{11}} + i p^2 \frac{\pi w_0^2}{2a^2} \right) - e^{i\pi r(x+x_0)/a} \mathcal{J}_3 \left( p \left[ \frac{\pi(x+x_0)}{2a} + \frac{2\pi r z}{z_{11}} + i r \frac{\pi w_0^2}{2a^2} \right] \middle| p^2 \frac{2z}{z_{11}} + i p^2 \frac{\pi w_0^2}{2a^2} \right) \right\} \quad (39)$$

for any specified positive integer  $p$ . Now, let  $z = z_{pq} + \Delta z_p$ , where now  $-z_{11}/2p \leq \Delta z_p \leq z_{11}/2p$ . The periodicity properties (B.3) and (B.4) allow us to replace  $z$  by  $\Delta z_p$  in the arguments of the theta-functions in (39). Subsequently applying (B.8) results in

$$E_y(x,z) = \frac{w_0}{pf(\Delta z_p)} e^{-ikz} \sum_{r=0}^{p-1} e^{2\pi i r^2 q/p} \left\{ e^{-\frac{(x-x_0)^2}{2f^2(\Delta z_p)}} \vartheta_3 \left( \frac{ia(x-x_0)}{pf^2(\Delta z_p)} - \frac{\pi r}{p} \left| \frac{2ia^2}{\pi p^2 f^2(\Delta z_p)} \right. \right) - e^{-\frac{(x+x_0)^2}{2f^2(\Delta z_p)}} \vartheta_3 \left( \frac{ia(x+x_0)}{pf^2(\Delta z_p)} - \frac{\pi r}{p} \left| \frac{2ia^2}{\pi p^2 f^2(\Delta z_p)} \right. \right) \right\} \quad (40)$$

where  $f$  is defined in (35) as before. For  $p=1$ , this reduces to (34) as expected. Finally, through the use of (B.12) we obtain

$$E_y(x,z) = \frac{w_0}{f(\Delta z_p)} e^{-ikz} \frac{1}{p} \sum_{r=0}^{p-1} e^{2\pi i r^2 q/p} \left\{ \sum_{m=-\infty}^{\infty} e^{-2\pi i m r/p} \left[ e^{-\frac{(x-x_0+2ma/p)^2}{2f^2(\Delta z_p)}} - e^{-\frac{(x+x_0+2ma/p)^2}{2f^2(\Delta z_p)}} \right] \right\} \quad (41)$$

Clearly, equation (41) represents a string of Fresnel images at  $z_{pq}$ , broadened by their additional propagation distance  $\Delta z_p$  as evidenced by the factor  $f(\Delta z_p)$  (compare (26)-(27)). A slight rearrangement of (41) yields a single summation (letting  $m \rightarrow -n$ ):

$$E_y(x,z) = \frac{w_0}{f(\Delta z_p)} e^{-ikz} \sum_{n=-\infty}^{\infty} c_n(p,q) \left\{ e^{-\frac{(x-x_0-2na/p)^2}{2f^2(\Delta z_p)}} - e^{-\frac{(x+x_0-2na/p)^2}{2f^2(\Delta z_p)}} \right\} \quad (42)$$

where  $c_n(p,q)$  is given by (27).

How, then, is  $p$  to be chosen? Our goal is to minimize the number of terms of the series (42) required to give a specified accuracy.

The series (42) should be taken from  $n = -N$  to  $N + 1$ , with  $N$  chosen so as to have a relative error term less than a given magnitude, say  $10^{-5}$ .

This criterion can be specified a priori as

$$N = [3 p w (\Delta z_p)/a] + 1 \quad (43)$$

where the square brackets denote the greatest integer less than or equal to the enclosed quantity, and  $w(\cdot)$  is the function given in (38). This criterion can be obtained by estimating the magnitudes of the successive terms in (42). Now, as  $z_p$  varies from 0 to  $\pm z_{p1}/2p = \pm z_{p1}/2$ , (43) varies from  $3pw_0/a + 1$  to

$$\frac{6}{\pi} \frac{a}{w_0} \left( 1 + \frac{\pi^2 p^2 w_0^4}{4a^4} \right)^{\frac{1}{2}}.$$

If  $p < a/2w_0$ , then  $N$  may vary between 1 and a maximum of about  $6a/\pi w_0$ , as  $\Delta z_p$  varies on the interval  $[-z_{p1}/2, +z_{p1}/2]$ . On the other hand, if  $p > 2a^2/\pi w_0^2$ ,  $N$  varies from a minimum of at least  $4a/\pi w_0$  to a maximum of at least  $6\sqrt{2} a/\pi w_0$ . Such large values of  $p$  are thus clearly undesirable for efficient field computations (because more images of the Gaussian beam are fitted inside the waveguide than can be accommodated without severe overlap). Although small values of  $p$  may give very small values of  $\Delta z_p$  for certain values of  $z$ , a single choice of  $p$  for all  $z$  results in a simpler computer program. Thus, the choice of

$$p = [a/w_0] + 1$$

appears to us to be nearly optimal.

## V. NUMERICAL RESULTS

Numerical results for  $0 \leq z \leq z_{g1}$  were computed for a symmetrical Gaussian beam

$$E_y(x,0) = e^{-\frac{(x-a/2)^2}{2w_0^2}}$$

for a waveguide with  $ka = 973.4$ ,  $kw_0 = 110.3$ . Computations were made using both an exact mode series (cf. (14)) and the hybrid-image representation (42). The two methods gave graphically indistinguishable results over this range, which are displayed in Fig. 5. Note that 5 or 6 is the maximum distinguishable number of beams in this case, and is a suitable choice for  $p$ .

Figure 6 shows that for very large values of  $z$ , the accuracy of the paraxial approximation has begun to deteriorate slightly. In a future paper, we will examine how to obtain closed-form expressions for this correction, but meanwhile we note that even for  $z \approx 250z_{11}$ , the accuracy of the paraxial expression is quite good. If we take this example to model an optical waveguide with  $a = 100\mu$ ,  $w_0 = 7.07\mu$ , the distance  $250z_{11}$  represents about a 50 m length of waveguide which of course is a huge number of wavelengths. We thus see that the paraxial approximation is capable of excellent accuracy over modest lengths of waveguide, even at optical frequencies.

## VI. CONCLUSION

We have described a hybrid technique for computing the fields of a paraxial beam propagating in a multimode waveguide for very long distances. The method relies on the periodic Fourier and Fresnel imaging properties of the guide, and is highly efficient for beams of moderate width compared to either full modal or ray approaches. Numerical comparisons have confirmed the accuracy of this method.

This approach should be susceptible to generalizations in several directions. For a beam with oblique incidence (as in [6]), the parabolic approximation of section II can be modified when the dominant propagation factor in the  $z$ -direction is other than  $\exp(-ikz)$  as indicated in [12]. Higher-order corrections to the paraxial solution for a dielectric slab similar to those for the metallic guide given in Section II can also be obtained. Slowly-varying guide widths and inhomogeneous refractive index profiles should also be tractable by similar methods. Investigations into these areas are currently being made, as is the generalization to waveguides of circular symmetry.

## APPENDIX A

## THE PARAXIAL APPROXIMATION FOR A DIELECTRIC SLAB

Consider the step-index dielectric slab waveguide shown in Fig. 7. The slab has thickness  $b$  and refractive index  $n_0$ . The cladding index is  $n_1$ , and both media are assumed to be nonmagnetic. The TE modes for this waveguide have the field distribution [1]

$$E_y = \begin{cases} e^{-ik_\alpha z} A e^{k\sqrt{\alpha^2 - n_1^2} x} \sin \phi(\alpha) & x \leq 0 \\ e^{-ik_\alpha z} A \sin \left[ k\sqrt{n_0^2 - \alpha^2} x + \phi(\alpha) \right] & 0 \leq x \leq b \\ e^{-ik_\alpha z} A \sin \left[ k\sqrt{n_0^2 - \alpha^2} b + \phi(\alpha) \right] e^{-k\sqrt{\alpha^2 - n_1^2} (x-b)} & x \geq b \end{cases} \quad (\text{A.1})$$

where  $A$  is an arbitrary constant amplitude. Here  $k$  is the wavenumber of free space,  $k_\alpha$  is the propagation constant of the mode, and  $\phi(\alpha)$  is the phase shift associated with the Goos-Hänchen effect:

$$\phi(\alpha) = \sin^{-1} \left[ kb \sqrt{n_0^2 - \alpha^2} / V \right] \quad (\text{A.2})$$

where  $V$  is the so-called normalized frequency :

$$V = kb \sqrt{n_0^2 - n_1^2} \quad (\text{A.3})$$

Note that  $V \gg 1$  for a highly multimode guide.

The characteristic equation which determines the eigenvalues  $\alpha$  is obtained by requiring  $H_z$  to be continuous at  $x = b$ :

$$\sin \left[ k\sqrt{n_0^2 - \alpha^2} b + 2\phi(\alpha) \right] = 0 \quad (\text{A.4})$$

The paraxial approximation to these modes ( $\alpha \approx n_0$ ) is found as in [10]

by reckoning  $\phi(\alpha)$  to be small. From (A.2) and (A.4), we then obtain approximately

$$\sin \left[ k \sqrt{n_0^2 - \alpha^2} b (1 + 2/V) \right] = 0$$

or

$$\alpha_m = \sqrt{n_0^2 - \frac{m^2 \pi^2}{k^2 b^2 (1 + 2/V)^2}} \quad (\text{A.5})$$

i.e., the propagation constants for a parallel-plate waveguide of slightly larger width  $a = b(1 + 2/V)$ . The corresponding field within the slab is, from (A.1),

$$e^{-ik\alpha_m z} A \sin \left[ k \sqrt{n_0^2 - \alpha^2} (x + b/V) \right] \quad 0 \leq x \leq b \quad (\text{A.6})$$

Here we have

$$\alpha_m = n_0 - \frac{m^2 \pi^2}{2n_0 k^2 b^2 (1 + 2/V)^2} + 0 \left[ \frac{m^4 \pi^4}{k^2 b^2 V^3 (1 + 2/V)^5} \right] \quad (\text{A.7})$$

$$0 \left[ \frac{m^4 \pi^4}{k^4 b^4 (1 + 2/V)^4} \right]$$

For most optical waveguides the first error term is likely to be the larger, but in any case we require

$$k^2 b^2 V^3 \gg 1 \quad \text{and} \quad k^4 b^4 \gg 1$$

## APPENDIX B

PROPERTIES OF  $c_n(p,q)$  and  $\vartheta_3(z|\tau)$ 

In this Appendix, we derive a number of useful properties of the Gaussian sums  $c_n(p,q)$  defined by (27), and the theta-function  $\vartheta_3(z|\tau)$ , defined by

$$\vartheta_3(z|\tau) = \sum_{m=-\infty}^{\infty} e^{m^2\pi i\tau + 2miz} \quad (\text{B.1})$$

where, for our purposes,  $z$  is an arbitrary complex number, while  $\tau$  lies in the upper half-plane  $\text{Im}(\tau) \geq 0$ . If  $\tau$  lies on the real axis, we likewise require that  $z$  be real, and in this case  $\vartheta_3(z|\tau)$  must be treated as a generalized function.

From Whittaker and Watson [26], we can obtain a number of periodicity and parity relations:

$$\vartheta_3(z|\tau) = \vartheta_3(-z|\tau) \quad (\text{B.2})$$

$$\vartheta_3(z|\tau + 2n) = \vartheta_3(z|\tau) \quad (\text{B.3})$$

$$\vartheta_3(z + n\pi|\tau) = \vartheta_3(z|\tau) \quad (\text{B.4})$$

$$\vartheta_3(z + n\pi\tau|\tau) = e^{-\pi in^2\tau - 2inz} \vartheta_3(z|\tau) \quad (\text{B.5})$$

All four relations are easy consequences of the definition (B.1). It is also interesting to note that  $\vartheta_3$  satisfies the parabolic equation

$$\frac{\pi i}{4} \frac{\partial^2 \vartheta_3(z|\tau)}{\partial z^2} + \frac{\partial \vartheta_3}{\partial \tau} = 0 \quad (\text{B.6})$$

which is obtained from the Helmholtz equation in the paraxial approximation, and is similarly easily verified (cf. eqn.(8)).

For real  $z$ ,  $\mathcal{U}_3$  at  $\tau=0$  (as a generalized function) can be evaluated as [24],[30]:

$$\mathcal{U}_3(z|0) = \sum_{m=-\infty}^{\infty} e^{2miz} = \pi \sum_{n=-\infty}^{\infty} \delta(z - n\pi) \quad (\text{B.7})$$

Another useful relation, which holds for general  $z$  and  $\tau$ , is obtained from Jacobi's imaginary transformation [26]:

$$\mathcal{U}_3(z|\tau) = \tau^{-\frac{1}{2}} e^{i\pi/4 + z^2/\pi i\tau} \mathcal{U}_3\left(\frac{z}{\tau} \middle| -\frac{1}{\tau}\right) \quad (\text{B.8})$$

This relation can be verified using the Poisson summation formula [24].

The identities which form the basis for the "image-splitting" properties of the theta -function can be deduced from a more general expression given by Krazer [31] (see also [32]). These relations, which might be referred to as modular relations, are

$$\mathcal{U}_3(z|\tau) = \sum_{r=0}^{p-1} e^{\pi i r^2 \tau + 2irz} \mathcal{U}_3(p[z + \pi r\tau] | p^2 \tau) \quad (\text{B.9})$$

$$\mathcal{U}_3(z|\tau) = \frac{1}{p} \sum_{r=0}^{p-1} \mathcal{U}_3\left(\frac{z + \pi r}{p} \middle| \frac{\tau}{p^2}\right) \quad (\text{B.10})$$

Equation (B.9) is verified by writing  $m = p\ell + r$ ,  $r = 0, 1, \dots, (p-1)$  in (B.1); (B.10) follows by substituting (B.1) into the right hand side. Actually (B.9) and (B.10) can also be derived from each other using (B.8) as well.

An integral which the authors could not find in the literature is given below:

$$\int_{-\infty}^{\infty} e^{-ax^2+bx} \mathcal{U}_3^{\ell}(x|\tau) dx = \sqrt{\frac{\pi}{a}} e^{b^2/4a} \mathcal{U}_3^{\ell}\left(\frac{b}{2a} \mid \tau + \frac{i}{\pi a}\right) \quad (\text{B.11})$$

The derivation is straightforward, proceeding by integrating (B.1) term-by-term.

Finally, we note that

$$\mathcal{U}_3^{\ell}(iz|i\tau) = e^{z^2/\pi\tau} \sum_{m=-\infty}^{\infty} e^{-(z+m\pi\tau)^2/\pi\tau} \quad (\text{B.12})$$

i.e.,  $\mathcal{U}_3^{\ell}$  can be related to a string of displaced Gaussian functions.

The Gaussian sums  $c_n(p,q)$  depend on the prime factorizations of the integers  $p$  and  $q$ . The properties of these sums can be derived by following methods outlined in [25] or [33] for the special case of  $c_0(p,q)$ . Here, we will only present the results, and refer the interested reader to [25] and [33] for the methods of proof (see also [34], [35] and [38]).

In order to describe the properties of  $c_n(p,q)$ , we will use the following notations from number theory [25]:

- $k|m$ :  $k$  divides  $m$  (without remainder)
- $k \nmid m$ :  $k$  does not divide  $m$
- $(k,m)$ : greatest common factor of  $k$  and  $m$
- $a \equiv b \pmod{m}$ :  $m|(a-b)$
- $(k|m)$ : Legendre's symbol defined for odd primes  $m$ ;  
 $(k|m) = +1$  if  $t^2 \equiv k \pmod{m}$  for some integer  $t$   
and  $k \not\equiv 0 \pmod{m}$ .  
 $(k|m) = -1$  if  $t^2 \not\equiv k \pmod{m}$  for any integer  $t$ .  
 $(0|m) = 0$ .

The following properties are elementary:

$$c_n(p, q + p) = c_n(p, q) \quad (\text{B.13})$$

$$c_{n+p}(p, q) = c_n(p, q) \quad (\text{B.14})$$

$$c_n(1, q) = 1 \quad (\text{B.15})$$

$$c_n(p, 0) = \begin{cases} 1 & p \mid n \\ 0 & p \nmid n \end{cases} \quad (\text{B.16})$$

Reciprocity law (for  $q$  odd):

$$c_n(p, q) = \sqrt{\frac{q}{2p}} e^{\pi i/4 - \pi i n^2/2p} [1 + e^{-\pi i p q/2 - \pi i n}] c_n^*(q, p) \quad (\text{B.17})$$

where  $*$  denotes complex conjugate. In particular, from (B.15) and (B.17) there follows

$$c_n(p, 1) = \frac{e^{\pi i/4 - \pi i n^2/2p}}{\sqrt{2p}} [1 + e^{-\pi i p/2 - \pi i n}] \quad (\text{B.18})$$

We need only consider the case when  $(p, q) = 1$ , because of

$$c_n(kp, kq) = \begin{cases} c_{n/k}(p, q) & k \mid n \\ 0 & k \nmid n \end{cases} \quad (\text{B.19})$$

Also, we need only consider the case when  $p$  is odd or a power of 2, because if  $(p_1, p_2) = 1$ ,

$$c_n(p_1 p_2, q) = c_n(p_1, q p_2) c_n(p_2, q p_1) \quad (\text{B.20})$$

These cases can be reduced to the case  $n=0$ , since if  $p$  is odd and  $(p, q) = 1$ , then

$$c_n(p, q) = e^{2\pi i n^2 q_0/p} c_0(p, q) \quad (\text{B.21})$$

where  $q_0$  is the solution (unique mod  $p$ ) of

$$4q_0 \equiv -1 \pmod{p}.$$

If  $p = 2^\alpha$  and  $(p, q) = 1$ , then

$$c_n(2^\alpha, q) = \begin{cases} \frac{1 - e^{-\pi i n}}{2} & \alpha = 1 \\ 2^{-\alpha/2} [1 + e^{\pi i (q+n)/2}] \left( \frac{1 + e^{-\pi i n}}{2} \right) e^{-2\pi i n^2 (2^{-\alpha-2} + p_0)/q} & \alpha = 2, 4, 6, \dots \\ 2^{-(\alpha-1)/2} e^{\pi i q/4} \left( \frac{1 + e^{-\pi i n}}{2} \right) e^{-2\pi i n^2 (2^{-\alpha-2} + p_0)/q} & \alpha = 3, 5, 7, \dots \end{cases} \quad (\text{B.22})$$

where  $p_0$  is the solution (unique mod  $q$ ) of

$$2^{\alpha+2} p_0 \equiv -1 \pmod{q}.$$

Further factoring of odd  $p$  using (B.20) results in  $c_0(p^\alpha, q)$ , where  $p$  is an odd prime and  $(q, p) = 1$ . In this case

$$c_0(p^\alpha, q) = \begin{cases} p^{-\alpha/2} & \alpha = 0, 2, 4, \dots \\ p^{-\alpha/2} e^{\pi i (p-1)^2/8} (q|p) & \alpha = 1, 3, 5, \dots \end{cases} \quad (\text{B.23})$$

From the foregoing properties we can deduce that if  $(p, q) = 1$ ,

$$|c_n(p, q)| = p^{-\frac{1}{2}} \quad (\text{B.24})$$

if  $p$  is odd, and

$$|c_n(p, q)| = \begin{cases} 0 \\ 2^{-(\alpha-1)/2} \tilde{p}^{-\frac{1}{2}} \end{cases} \quad (\text{B.25})$$

alternately in  $n$  if  $p = \tilde{p}^{2^\alpha}$  with  $\tilde{p}$  odd and  $\alpha \geq 1$ . We can conclude from this that the power in the original image is equally divided among all Fourier or Fresnel images which have a non-vanishing amplitude.

## Figure Captions

Fig. 1: Parallel-plate waveguide.

Fig. 2: Imaging of a nonsymmetrical field distribution.

(a) Input function  $E_Y(x,0)$ .

(b)  $E_Y(x,z_{21}) = E_Y(a-x,0)$  (Inverted image).

(c) The three components of  $E_Y(x,z_{31})$ ;

$$E_Y(x,z_{31}) = \frac{i}{\sqrt{3}} E_Y(x,0) + \frac{e^{-i\pi/6}}{\sqrt{3}} \left\{ \begin{array}{l} -E_Y(\frac{2a}{3} - x, 0) ; \quad 0 \leq x \leq \frac{2a}{3} \\ E_Y(x - \frac{2a}{3}, 0) ; \quad \frac{2a}{3} \leq x \leq a \end{array} \right\} \\ + \frac{e^{-i\pi/6}}{\sqrt{3}} \left\{ \begin{array}{l} E_Y(x + \frac{2a}{3}, 0) ; \quad 0 \leq x \leq \frac{a}{3} \\ -E_Y(\frac{4a}{3} - x, 0) ; \quad \frac{a}{3} \leq x \leq a \end{array} \right\}$$

(d) The two components of  $E_Y(x,z_{41})$ ;

$$E_Y(x,z_{41}) = [e^{i\pi/4} E_Y(x,0) + e^{3\pi i/4} E_Y(a-x,0)]/\sqrt{2}.$$

Fig. 3: Imaging of a symmetric field distribution.

(a)  $|E_Y(x,0)| = |E_Y(x,z_{21})| = |E_Y(x,z_{41})| = |E_Y(x,z_{81})|$ .

(b) The three components of  $E_Y(x,z_{31})$ .

Fig. 4: Overlapping of original and image beams in overmoded waveguide.

Fig. 5: Evaluation of power distribution of Gaussian beam over 1/8 - cycle:

$ka = 973.39$ ;  $kw_0 = 110.3$ . (a)  $z/z_{11} = 0$ ; (b)  $3/512$ ; (c)  $8/512$ ;  
(d)  $13/512$ ; (e)  $16/512$ ; (f)  $22/512$ ; (g)  $28/512$ ; (h)  $32/512$ ;  
(i)  $55/512$ ; (j)  $64/512$ .

Fig. 6: Exact and approximate power patterns at large axial distance;  
 $ka = 1538.23$ ;  $kw_0 = 174.3$ ;  $z/z_{11} = 250.119$ .
