MAXIMUM NORM ANALYSIS OF OVERLAPPING NON-MATCHING GRID DISCRETIZATIONS OF ELLIPTIC EQUATIONS*

XIAO-CHUAN CAI†, TAREK P. MATHEW‡ AND MARCUS V. SARKIS§

Abstract. In this paper, we provide a maximum norm analysis of a finite difference scheme defined on overlapping non-matching grids for second order elliptic problems. We consider a domain which is the union of \( p \) overlapping subdomains where each subdomain has its own independently generated grid. The grid points on the subdomain boundaries need not match the grid points from adjacent subdomains. To obtain a global finite difference discretization of the elliptic problem, we employ standard stable finite difference discretizations on each of the overlapping subdomains and the different subproblems are coupled by enforcing continuity of the solutions across the boundary of each subdomain, by interpolating the discrete solution on adjacent subdomains. If the subdomain finite difference schemes satisfy a strong discrete maximum principle and if the overlap is sufficiently large, we show that the global discretization converges in optimal order corresponding to the largest truncation errors of the local interpolation maps and discretizations. Our discretization scheme and the corresponding theory allows any combination of lower order and higher order finite difference schemes in different subdomains. We describe also how the resulting linear system can be solved iteratively by a parallel Schwarz alternating method or a Schwarz preconditioned Krylov subspace iterative method. Several numerical results are included to support the theory.

1. Introduction. In recent years, much interest within the domain decomposition literature has focused on techniques for obtaining global discretizations of elliptic equations by combining discretizations on local non-overlapping or overlapping subdomains triangulated by non-matching grids. If each subdomain is independently triangulated using grids most suitable to its geometry or the local smoothness of the solution, then the resulting grids may not match at the boundaries. In the domain decomposition literature, techniques based on “Lagrange multipliers” and “mortar spaces” have been devised to “glue” together high accuracy local discretizations (for instance, based on spectral methods or \( p \)-version finite elements), see for instance, [2, 4, 5, 8, 9, 23], and also lower order local discretizations based on \( h \)-version finite elements, see for instance, [1, 7, 20, 31]. By contrast, in the finite difference literature, even prior to the development of domain decomposition techniques, several early works have focused on discretizations on non-matching composite grids, see [11, 16, 18, 28, 29]. Even though the available theory is limited, several large computations have shown that non-matching grid techniques have tremendous advantages over the traditional matching grid methods due to the time saved on the grid generation stage of the computation, especially

for problems with complex geometry ([19, 29]).

In [28], Starius provided an analysis for the two subdomain case, and our purpose in this paper is to extend the result of Starius on the maximum norm stability of global finite difference discretizations of elliptic equations, to the case of many subdomains. The extension we consider will be applicable to domains with general shapes, involve an arbitrary number of composite subgrids, and allow local finite difference schemes of any order, provided the discretizations satisfy locally a maximum principle and the overlap between the subdomains is sufficiently large. Further, the analysis, based on constructing a contraction mapping, will permit parallel solution of the subgrid problems iteratively.

The linear elliptic equation we consider will be of the following form on a domain \( \Omega \) in \( \mathbb{R}^2 \) or \( \mathbb{R}^3 \):

\[
\begin{cases}
Lu - \Delta u + \vec{b}(x) \cdot \nabla u + c(x)u = f(x) & \text{in } \Omega \\
u = g & \text{on } \partial \Omega.
\end{cases}
\]  

Throughout the rest of this paper, we will assume that \( c(x) \geq c_0 > 0 \) on \( \Omega \), and that the forcing term \( f \), the boundary value function \( g \), the coefficients \( \vec{b} \) and \( c \), and the exact solution \( u \) are smooth. On each subdomain, we will consider local discretizations that satisfy a discrete maximum principle.

One of the fundamental issues in studying non-matching grid methods is to understand the relation between the order of the global discretization error, the orders of the subdomain discretization errors, the orders of the interpolation errors between non-matching subgrids, and the size of the overlap. Suppose that \( \Omega \) is the union of \( p \) overlapping subdomains \( \Omega'_1, \ldots, \Omega'_p \). Let \( h_i \) be the mesh size of subdomain \( \Omega'_i \), and let \( p_i \) and \( q_i \) be the orders of the discretization and interpolation errors on \( \Omega'_i \), then we show in this paper that the maximum norm of the global error is bounded by

\[
C \left( 1 + \frac{\sigma}{1 - \delta_0} \right) \left( \sum_{i=1}^{p} h_i^{p_i} \| u \|_{p_i+1, \infty} + \sum_{i=1}^{p} h_i^{q_i} \| u \|_{q_i+1, \infty} \right).
\]

Here \( \sigma \) is a bound for the maximum norm of the subdomain interpolation operators. \( \delta_0 < 1 \) is a parameter that depends on \( \sigma \) and on a contraction factor \( \rho \) associated with homogeneous solutions of subdomain elliptic equations. For elliptic equations with \( c(x) \geq c_0 > 0 \), it is known that the maximum norm of a homogeneous solution in the true interior of a domain is bounded by the maximum norm of its boundary data multiplied by a factor \( 0 < \rho < 1 \), see for instance Smoller [27] or Lions [22]. For the discrete case, see [15, 25]. The parameter \( \delta_0 \) is the product of \( \sigma \) with the largest factor \( \rho \) from different subdomains. Thus, factor \( \delta_0 \) may depend on the size of the overlap between the subdomains, while \( \sigma \) may depend on the choice of the local grids.

The method and the theory described in this paper are quite different from the mortar based approach developed in [7]. In the mortar method, the discretization error is proved to be totally independent of the overlap size. Whereas the method to be studied in this paper has some degree of dependency on the overlap size and is a lot easier to implement than any of the mortar type methods. The mortar theory of [7]
is valid only for the two-subdomain case involving simple interfaces without corner points, while the maximum principle based theory developed in this paper applies for any number of subdomains in both $R^2$ and $R^3$.

Although the focus of this paper is on the accuracy of the overlapping non-matching grid method, we will include a short discussion on Schwarz type iterative methods for solving the resulting linear system of equations. We prove that if the overlap is sufficiently large, the convergence of the Schwarz method is independent of the mesh sizes. Related topics can also be found in the book [26].

The rest of the paper is organized as follows. In Section 2, we describe a finite difference procedure for obtaining a global discretization on non-matching composite grids, see [11, 28]. In Section 3, we describe a technique for analyzing the stability of the global discretization. In Section 4, we apply the stability result of Section 3 to derive bounds for the accuracy of the global discrete solution. In Section 5, we describe two iterative procedures for solving the resulting linear system satisfied by the global discrete solution, by using a parallel Schwarz alternating method and an additive Schwarz preconditioned Krylov subspace iterative method. Finally, in Section 6, we present the results of sample numerical tests.

2. Discretization on overlapping non-matching grids. The global discretization method we use is the composite grid method, see for instance, Starius [28] and Cheshire and Henshaw [11]. It involves independently discretizing the elliptic equation $Lu = f$ on each of the subgrids and coupling the discretizations by requiring continuity of the solutions across the boundaries.

Given a domain $\Omega$, we first choose a partition of $\Omega$ into $p$ non-overlapping subdomains such that

$$ \overline{\Omega} = \bigcup_{i=1}^{p} \overline{\Omega_i}, \quad \Omega_i \cap \Omega_j = \emptyset, \quad \text{for } j \neq i. $$

We then enlarge each subdomain $\Omega_i$ to include all points in $\Omega$ within a distance $\theta > 0$ and denote the resulting enlarged subdomain by $\Omega_i'$

$$ \Omega_i' = \{ (x, y) \in \Omega : \text{dist}((x, y), \Omega_i) \leq \theta \}. $$

Thus the enlarged domains will satisfy

$$ \Omega \subset \left( \bigcup_{i=1}^{p} \Omega_i' \right). $$

On each subdomain $\Omega_i'$ we independently construct a grid of size $h_i$. We will use $\Omega_i', h_i$ to denote the grid on $\Omega_i'$, for $i = 1, \ldots, p$. The grid points on the boundary $\partial \Omega_i'$ need not align with the grid points in the adjacent subdomains, see Fig 1.

On grid $\Omega_i', h_i$, we use $U_{i, h_i}$ to denote the discrete solution approximating the exact solution $u$ on $\Omega_i', h_i$. The global solution $U_h$ is then denoted as the collection of local solutions

$$ U_h = (U_{h_1}, \ldots, U_{h_p}) . $$
We use the notation $\Gamma_i$ to denote the portion of the boundary $\partial \Omega_i'$ intersecting $\partial \Omega$, i.e.,

$$\Gamma_i \equiv \partial \Omega_i' \cap \partial \Omega.$$  

We can then partition $\partial \Omega_i'$ into two pieces, $\Gamma_i$ and its complement $\partial \Omega_i' \setminus \Gamma_i$:

$$\partial \Omega_i' = (\partial \Omega_i' \cap \partial \Omega) \cup (\partial \Omega_i' \setminus \Omega) \cup (\partial \Omega_i' \setminus \Gamma_i).$$

We use $\Gamma_{i,h_i}$ to denote the grid on $\Gamma_i$.

To motivate the composite grid discretization, we observe that the solution $u(x)$ of the elliptic equation (1) satisfies

$$\begin{cases}
Lu_i &= f_i, \quad \text{on } \Omega_i' \\
      u_i &= g_i, \quad \text{on } \Gamma_i \\
      u_i &= u \quad \text{on } \partial \Omega_i' \setminus \Gamma_i,
\end{cases}$$

where $u_i$ denotes the continuous restriction of $u$ to $\Omega_i'$, where $f_i$ is the restriction of $f$ to $\Omega_i'$, and $g_i$ is the restriction of $g$ to $\Gamma_i$.

Analogous to the continuous case above, the local discretization on $\Omega_{i,h_i}'$ of problem (1) in the composite grid method will approximate the above problem

$$\begin{cases}
L_{h_i} U_{h_i} &= f_{h_i}, \quad \text{on } \Omega_{i,h_i}' \\
U_{h_i} &= g_{h_i}, \quad \text{on } \Gamma_{i,h_i}' \\
U_{h_i} &= P^i U_h \quad \text{on } \partial \Omega_{i,h_i}' \setminus \Gamma_{i,h_i},
\end{cases}$$

where $f_{h_i}$ is the restriction of the forcing term $f$ to the grid points in $\Omega_{i,h_i}'$, where $g_{h_i}$ is the restriction of the Dirichlet boundary data $g$ to the grid points in $\Gamma_{i,h_i}'$ and $P^i U_h$ will be suitably chosen as an interpolation of the discrete solution $U_h$ to enforce continuity.
of the local solution. If a grid point in \(\partial \Omega'_{i,h_i}\) matches with a grid point in an adjacent grid \(\Omega'_{j,h_j}\), then \(I^i U_h\) would ideally be chosen to equal the grid value of \(U_{h_j}\) at that grid point. However, for non-matching grids, we define \(I^i U_h\) as an interpolation of the grid values of \(U_{h_j}\) on adjacent grid points.

**Assumption A1 (Truncation error of local discretizations):** We assume that the local discretizations have a truncation error \(\alpha_i(x)\) of order \(p_i\) at a point \(x\) in \(\Omega'_{i,h_i}\).

More specifically, if \(u(x)\) is a smooth function, and \(u_{h_i}\) denotes the restriction of \(u(x)\) to the grid points in \(\Omega'_{i,h_i}\), then we define the local truncation error \(\alpha_i(x)\) at grid point \(x\) by

\[
(L_{hi} u_{hi}) (x) = (Lu) (x) + \alpha_i(x).
\]

(4)

We assume that the local discretization scheme is chosen so that the truncation error \(\alpha_i(x)\) satisfies the following bounds

\[
\|\alpha_i(x)\|_{\infty} \leq C h_i^{p_i} \|u\|_{p_i+1, \infty, \Omega'_{i}}.
\]

Here \(\|u\|_{p_i+1, \infty, \Omega'_{i}}\) denotes the Sobolev \(W^{p_i+1, \infty}(\Omega'_{i})\) norm of \(u\) (Grisvard [17]).

We require intergrid interpolation maps \(I^i\) for \(i = 1, \ldots, p\), to define the boundary data \(I^i U_h\) in the global discretization (7), where \(I^i U_h\) uses the value of \(U_{h_j}\) at grid points in the adjacent domains \(\Omega'_{j,h_j}\) for \(j \neq i\). This interpolation map \(I^i\) is a linear transformation

\[
I^i : U_h \rightarrow U_{h_i, \partial \Omega'_{i} \setminus \Gamma_{i,h_i}}.
\]

**Assumptions A2 (Subgrid interpolation):** We assume that the interpolation map \(I^i\) does not use values of \(U_{h_i}\) in \(\Omega'_{i,h_i}\), and further, that \(I^i\) only uses nodal values at grid points \(x\) in \(\cup_{j \neq i} \Omega'_{j,h_j}\), i.e., \(I^i\) does not use nodal values at grid points in the domains \(\{\Omega'_{j} \setminus \Omega_{j}\}_{j \neq i}\).

As an example, consider Fig 2. Let \(\times\) denote a grid point in \(\partial \Omega'_{i,h_i}\) and let \(\circ\) denote grid points in \(\Omega'_{j,h_j}\) for some \(j \neq i\). If \(\times\) lies in the convex hull of the grid points \(\circ\), then the interpolated value at \(\times\) can be obtained by linear interpolation of the nodal values on the triangle with vertices \(\circ\). We need to define a similar interpolation rule for each grid point on \(\partial \Omega'_{i} \setminus \Gamma_i\). For a suitable ordering of the grid points in \(\cup_{j=1}^{p} \Omega'_{j,h_j}\) and in \(\partial \Omega'_{i,h_i}\), the stencil is stored in the matrix \(I^i\).

**Remark 2.1.** The intergrid interpolation maps \(I^i\) may also be defined by matching various moments of the traces of the subdomain functions on the interfaces, as in mortar methods [7].

The maximum norm of each interpolation map \(I^i\) is denoted by \(\|I^i\|_{\infty}\). It corresponds to the largest absolute row sum of the matrix \(I^i\). We use \(\sigma\) to denote the largest of the maximum norms amongst all the interpolation maps

\[
\sigma \equiv \max_{i} \|I^i\|_{\infty}.
\]

(5)
For example, if $I^i U_h$ are all obtained at each grid point by piecewise linear interpolation of nodal values of $U_h$ on adjacent domains, then the linear interpolation stencil will correspond to a convex combination of three nodal values of $U_h$ in adjacent domains. For such a stencil, we obtain

$$\|I^i\|_\infty = 1, \quad \text{for } i = 1, \ldots, p,$$

and consequently $\sigma = 1$.

**Assumption A3 (Interpolation error):** The error $I - I^i$ of the interpolation operator $I^i$ is of order $q_i$.

Let $u(x)$ be a smooth function. Then the interpolation error $\beta_i(x)$ at a grid point $x \in \partial \Omega'_{i,h_i}$ is defined as

$$\beta_i(x) \equiv u(x) - (I^i u)(x).$$

This interpolation error $\beta_i(x)$ can be estimated using a Taylor series expansion of $u(x)$. We assume that the interpolation map $I^i$ is chosen such that the following bound holds for the interpolation error $\beta_i(x)$ at the point $x$

$$|\beta_i(x)| = |(I - I^i) u| \leq Ch_i^{q_i} \|u\|_{q_i+1,\infty, \Omega}, \quad (6)$$

where $\|\cdot\|_{q_i+1,\infty, \Omega}$ denotes the Sobolev $W^{q_i+1,\infty}(\Omega)$ norm and $C$ is a constant independent of $h_i$.

The global discretization for $U_h = (U_{h_1}, \ldots, U_{h_p})$ in the composite grid method is obtained by coupling the local discretizations by requiring that the solution "matches" the interpolation of the discrete solution from adjacent grids on $\partial \Omega'_{i,h_i} \setminus \Gamma_{i,h_i}.$

$$\begin{cases}
L_{h_i} U_{h_i} = f_{h_i}, & \text{on } \Omega'_{i,h_i} \\
U_{h_i} = g_{h_i}, & \text{on } \Gamma_{i,h_i} \\
U_{h_i} = I^i U_h, & \text{on } \partial \Omega'_{i,h_i} \setminus \Gamma_{i,h_i},
\end{cases} \quad (7)$$

for $i = 1, \ldots, p$. The above linear system can be solved iteratively, for instance, by using the Schwarz alternating procedure, see Section 5.
For example, in the case of two composite grids, our global discrete solution is denoted by \( U_h = (U_{h1}, U_{h2}) \), and it satisfies

\[
\begin{align*}
L_{h1}U_{h1} &= f_{h1}, & \text{on } \Omega'_{1,h1} \\
U_{h1} &= g_{h1}, & \text{on } \Gamma_{1,h1} \\
U_{h1} &= I^1(U_{h1}, U_{h2}), & \text{on } \partial\Omega'_{1,h1} \setminus \Gamma_{1,h1},
\end{align*}
\]

and

\[
\begin{align*}
L_{h2}U_{h2} &= f_{h2}, & \text{on } \Omega'_{2,h2} \\
U_{h2} &= g_{h2}, & \text{on } \Gamma_{2,h2} \\
U_{h2} &= I^2(U_{h1}, U_{h2}), & \text{on } \partial\Omega'_{2,h2} \setminus \Gamma_{2,h2}.
\end{align*}
\]

If there are \( n_1 \) grid points in \( \Omega'_{1,h1} \) and \( n_2 \) grid points in \( \Omega'_{2,h2} \) (including all the grid points on the boundaries), then the above global discretization yields a system of \( n_1 + n_2 \) linear algebraic equations for the discrete solution \( U_h = (U_{h1}, U_{h2}) \), including the boundary conditions on \( \partial\Omega' \).

**Remark 2.2.** Due to the non-symmetric nature of the interpolation maps, the above global discretization does not yield a symmetric linear system in general, even if the local discretizations are symmetric.

**Remark 2.3.** If the subgrids match, then the global discretization just introduced reduces to the usual discretization on the whole domain. The global linear system can also be reduced by removing the redundant variables.

### 3. Maximum norm stability of the global discretization

In this section, we prove that the global discretization (7) is solvable, and further that it is stable in the maximum norm. We first state the assumptions under which this analysis is valid.

**Assumption B1 (Local stability):** We assume that the local finite difference discretizations (3) are chosen so that they are stable in the maximum norm.

More precisely, for \( i = 1, \ldots, p \), we assume that there exists a constant \( K_i \) independent of \( h_i \) such that if \( U_{h_i} \) solves

\[
\begin{align*}
L_{h_i}U_{h_i} &= f_{h_i}, & \text{in } \Omega'_{i,h_i} \\
U_{h_i} &= g_{h_i}, & \text{on } \partial\Omega'_{i,h_i}, \\
U_{h_i} &= z_{h_i}, & \text{on } \partial\Omega'_{i,h_i} \setminus \Gamma_{i,h_i},
\end{align*}
\]

then for \( i = 1, \ldots, p \)

\[
\|U_{h_i}\|_{\infty,\Omega'_{i,h_i}} \leq K_i \|f_{h_i}\|_{\infty,\Omega'_{i,h_i}} + \max\{\|g_{h_i}\|_{\infty,\Gamma_{i,h_i}}, \|z_{h_i}\|_{\infty,\partial\Omega'_{i,h_i} \setminus \Gamma_{i,h_i}}\}.
\]

We note that in the special case that \( f_{h_i} = 0 \), then the above stability assumption requires that a homogeneous solution \( U_{h_i} \) satisfies a weak discrete maximum principle

\[
\|U_{h_i}\|_{\infty,\Omega'_{i,h_i}} \leq \max\{\|g_{h_i}\|_{\infty,\Gamma_{i,h_i}}, \|z_{h_i}\|_{\infty,\partial\Omega'_{i,h_i} \setminus \Gamma_{i,h_i}}\}.
\]
Assumption B2 (Contraction factor for homogeneous solutions): We assume that the local discretizations satisfy a strong discrete maximum principle of the following form. If \( e_{h_i} \) is the solution of the following homogeneous problem on the overlapping domain \( \Omega_i' \)

\[
\begin{align*}
L_{h_i} e_{h_i} &= 0, & & \text{on } \Omega_i',
\end{align*}
\]

\[
\begin{align*}
e_{h_i} &= 0, & & \text{on } \Gamma_i, \\
e_{h_i} &= z_{h_i}, & & \text{on } \partial \Omega_i' \setminus \Gamma_i.
\end{align*}
\]

then in the non-overlapping domain \( \Omega_i \)

\[\|c_{h_i}\|_{\infty, \Omega_i} \leq \rho_i \|z_{h_i}\|_{\infty, \partial \Omega_i' \setminus \Gamma_i},\]

where \( 0 < \rho_i < 1 \) is a contraction factor for the error on the \( i \)'th grid.

We note that such a contraction estimate can be shown to hold for elliptic equations that have a nonzero zeroth order term \( c(x) \geq c_0 > 0 \) provided the overlap parameter \( \theta \) is sufficiently large where \( \Omega_i' = \{(x, y) \in \Omega : \text{dist}((x, y), \Omega_i) \leq \theta\} \), and provided \( h_i \) is sufficiently small, see [12, 24, 25].

Assumption B3 (Product of \( \sigma \) and \( \rho_i \)): Recall that \( \rho_i \) denotes the maximum norm contraction factor for each subdomain as in (8), and \( \sigma \) denotes the largest maximum norm of the interpolation maps, as in (5). We assume that

\[
\max_i (\rho_i \sigma) = \delta_0 < 1.
\]

We now describe the stability result for the global discretization.

**Lemma 3.1.** Let \( W_h = (W_{h_1}, \ldots, W_{h_p}) \) satisfy the following discrete equations

\[
\begin{align*}
L_{h_1} W_{h_1} &= f_{h_1}, & & \text{on } \Omega_i',
W_{h_i} &= g_{h_i}, & & \text{on } \Gamma_i, \\
W_{h_i} - I^i W_h &= z_{h_i}, & & \text{on } \partial \Omega_i' \setminus \Gamma_i.
\end{align*}
\]

If assumptions A1, A2, A3, B1, B2 and B3 hold, then

\[
\sum_{i=1}^p \|W_{h_i}\|_{\infty, \Omega_i', h_i} \leq \left(1 + \frac{\sigma}{1 - \delta_0}\right) \left(\sum_{i=1}^p K_i \|f_{h_i}\|_{\infty, \Omega_i'} + \sum_{i=1}^p \max\{\|g_{h_i}\|_{\infty, \Gamma_i}, \|z_{h_i}\|_{\infty, \partial \Omega_i' \setminus \Gamma_i}\}\right),
\]

where \( K_i, \sigma \) and \( \delta_0 \) are independent of \( h_i \).

**Proof.** We apply Picard's theorem on the existence of a fixed point for contraction mappings as follows, see for instance [3]. Let \( H \) be a complete metric space endowed with a metric \( d(\cdot, \cdot) \), and let \( T : H \to H \) be a contraction mapping satisfying

\[
d(TU, TV) \leq \delta_0 d(U, V),
\]
for all $U$ and $V$ in $\mathcal{H}$, where $0 < \delta_0 < 1$. Then, $T$ has a unique fixed point $U^* \in \mathcal{H}$ satisfying

$$TU^* = U^*,$$

and given any initial iterate $U^0 \in \mathcal{H}$ we have the estimate

$$d\left(U^0, U^*\right) \leq \frac{d\left(U^0, TU^0\right)}{1 - \delta_0}.$$

In order to apply Picard's contraction mapping principle, we define $\mathcal{H}$, a metric $d(\cdot, \cdot)$ and a contraction mapping $T : \mathcal{H} \to \mathcal{H}$ such that the solution of the discrete problem (9) is the fixed point of $T$. Accordingly, we define $\mathcal{H}$ as follows

$$\mathcal{H} = \left\{ W_h = (W_{h_1}, \ldots, W_{h_p}) : \begin{array}{ll}
L_{h_i}W_{h_i} &= f_{h_i}, \quad \text{in } \Omega'_{i,h_i} \\
W_{h_i} &= g_{h_i}, \quad \text{on } \Gamma_{i,h_i}
\end{array} \text{ for } i = 1, \ldots, p \right\},$$

and endow $\mathcal{H}$ with the metric

$$d\left(U_h, W_h\right) = \max_i \|U_{h_i} - W_{h_i}\|_{\infty, \Omega'_{i,h_i}} = \max_i \|U_{h_i} - W_{h_i}\|_{\infty, \partial \Omega'_{i,h_i}} = \max_i \|U_{h_i} - W_{h_i}\|_{\infty, \partial \Omega'_{i,h_i} \setminus \Gamma_i}.$$

We note that the second and third definitions of the metric (involving maximum on the boundary $\partial \Omega'_{i,h_i}$ or boundary segment $\partial \Omega'_{i,h_i} \setminus \Gamma_{i,h_i}$, respectively) are equivalent to the former by an application of the discrete maximum principle since

$$\begin{cases}
L_{h_i}U_{h_i} = f_{h_i}, \quad \text{in } \Omega'_{i,h_i} \\
L_{h_i}W_{h_i} = f_{h_i}, \quad \text{in } \Omega'_{i,h_i}
\end{cases} \implies L_{h_i}(U_{h_i} - W_{h_i}) = 0, \quad \text{in } \Omega'_{i,h_i},$$

and so by assumption B1

$$\|U_{h_i} - W_{h_i}\|_{\infty, \Omega'_{i,h_i}} = \|U_{h_i} - W_{h_i}\|_{\infty, \partial \Omega'_{i,h_i}} = \|U_{h_i} - W_{h_i}\|_{\infty, \partial \Omega'_{i,h_i} \setminus \Gamma_{i,h_i}}.$$

The latter holds since $U_{h_i} - W_{h_i} = 0$ on $\Gamma_{i,h_i}$.

We note that $\mathcal{H}$ is complete under the given metric, since $\mathcal{H}$ is an affine set (defined by linear constraints) in a Euclidean space endowed with the maximum norm. Given $U_h = (U_{h_1}, \ldots, U_{h_p}) \in \mathcal{H}$ we define our mapping $TU_h = W_h$ as follows

$$\begin{cases}
L_{h_i}W_{h_i} = f_{h_i}, \quad &\text{on } \Omega'_{i,h_i} \\
W_{h_i} = g_{h_i}, \quad &\text{on } \Gamma_{i,h_i} \\
W_{h_i} = P^iU_h + z_{h_i}, \quad &\text{on } \partial \Omega'_{i,h_i} \setminus \Gamma_{i,h_i}.
\end{cases} \quad (10)$$

Clearly $T : \mathcal{H} \to \mathcal{H}$. 

9
We now verify that $T$ is a contraction mapping. Accordingly, consider $X_h \in \mathcal{H}$ and $Y_h \in \mathcal{H}$. We estimate $d(TX_h, TY_h)$. Let $U_h = TX_h$ and $V_h = TY_h$. Using the definition of $T$ in equation (10) we note that

$$\begin{align*}
L_{h_i} (U_{h_i} - V_{h_i}) &= 0, & \text{in } \Omega'_{i,h_i}, \\
U_{h_i} - V_{h_i} &= 0, & \text{on } \Gamma_{i,h_i}, \\
U_{h_i} - V_{h_i} &= I^i (X_h - Y_h), & \text{in } \partial \Omega'_{i,h_i} \setminus \Gamma_{i,h_i}.
\end{align*}$$

Consequently, we obtain

$$\begin{align*}
\|U_{h_i} - V_{h_i}\|_{\infty, \partial \Omega'_{i,h_i} \cap \Gamma_{i,h_i}} &= \|I^i(X_h - Y_h)\|_{\infty, \partial \Omega'_{i,h_i} \cap \Gamma_{i,h_i}} \\
&\leq \sigma \|X_h - Y_h\|_{\infty, \cup_{j \neq i} \partial \Omega_{j,h_j}} \\
&\leq \sigma \max_{j \neq i} \|X_h - Y_h\|_{\infty, \partial \Omega_{j,h_j}} \\
&\leq \sigma \max_{j \neq i} \rho_j \|X_h - Y_h\|_{\infty, \partial \Omega'_{j,h_j}} \\
&\leq \delta_0 \max_{j \neq i} \|X_h - Y_h\|_{\infty, \partial \Omega'_{j,h_j}} \\
&\leq \delta_0 d(X_h, Y_h),
\end{align*}$$

where the fourth line follows by an application of assumption $A2$ on the contraction of homogeneous solutions. Taking maxima over all $i$ on the left hand side, we obtain

$$\begin{align*}
d(U_h, V_h) &= \max_i \|U_{h_i} - V_{h_i}\|_{\infty, \partial \Omega'_{i,h_i} \cap \Gamma_{i,h_i}} \\
&\leq \delta_0 d(X_h, Y_h).
\end{align*}$$

Since $U_h = TX_h$ and $V_h = TY_h$, and since $\delta_0 < 1$ by assumption $A3$, this verifies that $T$ satisfies a contraction property with contraction factor $\delta_0 < 1$.

Next, we verify that $U_h$ is a fixed point of this contraction mapping: Using the definition of $T$ in equation (10), we note that if $U_h$ is a fixed point of $T$ then $U_h$ satisfies

$$\begin{align*}
L_{h_i} U_{h_i} &= f_{h_i}, & \text{on } \Omega'_{i,h_i}, \\
U_{h_i} &= g_{h_i}, & \text{on } \Gamma_{i,h_i}, \\
U_{h_i} &= I^i U_h + z_{h_i}, & \text{on } \partial \Omega'_{i,h_i} \setminus \Gamma_{i,h_i}.
\end{align*}$$

Thus, the solution $U_h$ of system (9) is a fixed point of $T$.

As a final step in establishing the stability of the discrete system (9), we need to determine the distance $d(U^0, TU^0)$ for a suitable choice of initial iterate $U^0 \in \mathcal{H}$. We choose $U^0 = (U^0_{h_1}, \ldots, U^0_{h_n})$ as follows

$$\begin{align*}
L_{h_i} U^0_{h_i} &= f_{h_i}, & \text{on } \Omega'_{i,h_i}, \\
U^0_{h_i} &= g_{h_i}, & \text{on } \Gamma_{i,h_i}, \\
U^0_{h_i} &= z_{h_i}, & \text{on } \partial \Omega'_{i,h_i} \setminus \Gamma_{i,h_i}.
\end{align*}$$

Then, $TU^0$ satisfies

$$\begin{align*}
L_{h_i} (TU^0)_{h_i} &= f_{h_i}, & \text{on } \Omega'_{i,h_i}, \\
(TU^0)_{h_i} &= g_{h_i}, & \text{on } \Gamma_{i,h_i}, \\
(TU^0)_{h_i} - I^i U^0 &= z_{h_i}, & \text{on } \partial \Omega'_{i,h_i} \setminus \Gamma_{i,h_i}.
\end{align*}$$

10
Thus, \( U_{h_i}^0 - (TU^0)_{h_i} \) satisfies
\[
\begin{aligned}
L_{h_i}(U^0 - TU^0)_{h_i} &= 0, & & \text{on } \Omega'_{i,h_i} \\
(U^0 - TU^0)_{h_i} &= 0, & & \text{on } \Gamma_{i,h_i} \\
(U^0 - TU^0)_{h_i} &= I^iU^0, & & \text{on } \partial\Omega'_{i,h_i} \setminus \Gamma_{i,h_i}.
\end{aligned}
\]
Using the discrete maximum principle we obtain that
\[
\begin{aligned}
\| (U^0 - TU^0)_{h_i} \|_{\infty, \Omega'_{i,h_i}} &\leq \| I^iU^0 \|_{\infty, \Omega'_{i,h_i}} \\
&\leq \sigma \| U^0 \|_{\infty} \\
&\leq \sigma \left( \sum_{i=1}^{p} K_i \| f_{h_i} \|_{\infty} + \max \{ \| g_{h_i} \|_{\infty}, \| z_{h_i} \|_{\infty} \} \right).
\end{aligned}
\]
Thus
\[
d \left( U^0, TU^0 \right) \leq \sigma \left( \sum_{i=1}^{p} K_i \| f_{h_i} \|_{\infty} + \max \{ \| g_{h_i} \|_{\infty}, \| z_{h_i} \|_{\infty} \} \right),
\]
and so
\[
d \left( U^0, U_h \right) \leq \frac{\sigma}{1 - \delta_0} \left( \sum_{i=1}^{p} K_i \| f_{h_i} \|_{\infty} + \max \{ \| g_{h_i} \|_{\infty}, \| z_{h_i} \|_{\infty} \} \right),
\]
and using the definition of \( d (\cdot, \cdot) \), we obtain that
\[
\sum_{i=1}^{p} \| U_{h_i} \|_{\infty, \Omega'_{i,h_i}} \leq \left( 1 + \frac{\sigma}{1 - \delta_0} \right) \left( \sum_{i=1}^{p} K_i \| f_{h_i} \|_{\infty} + \max \{ \| g_{h_i} \|_{\infty}, \| z_{h_i} \|_{\infty} \} \right).
\]
This establishes the global stability of scheme (9). \( \square \)

4. Accuracy of the global discretization. In this section, we estimate the accuracy of the global discretization (7). We assume that the solution \( u(x) \) of the original elliptic problem (1) is sufficiently smooth. We have the following Theorem.

**Theorem 4.1.** Let \( u_h(x) \) denote the restriction of the exact solution \( u(x) \) of problem (1) to the composite grid. Let \( U_h \) denote the discrete solution. If assumptions B1, B2, B3 hold, and if assumptions A1, A2 and A3 hold, then the error \( u_{h_i} - U_{h_i} \) in the discrete solution satisfies the following bounds
\[
\sum_{i=1}^{p} \| u_{h_i} - U_{h_i} \|_{\infty} \leq C \left( 1 + \frac{\sigma}{1 - \delta_0} \right) \left( \sum_{i=1}^{p} K_i h_{i}^{p_i} \| u \|_{p_i+1,\infty} + \sum_{i=1}^{p} h_{i}^{q_i} \| u \|_{q_i+1,\infty} \right),
\]
where \( C, \sigma, K_i \) and \( \delta_0 \) are independent of \( h_i \).

**Proof.** We substitute \( u_h \) into the global discretization to obtain
\[
\begin{aligned}
L_{h_i} u_{h_i} &= f_{h_i} + \alpha_i, & & \text{on } \Omega'_{i,h_i} \\
u_{h_i} &= g_{h_i}, & & \text{on } \Gamma_{i,h_i} \\
u_{h_i} &= I^i u_h + \beta_i, & & \text{on } \partial\Omega'_{i,h_i} \setminus \Gamma_{i,h_i},
\end{aligned}
\]

where $\alpha_i$ are the local truncation errors. We define the error $e_h$ by subtracting the exact solution $u_h = (u_{h_1}, \ldots, u_{h_p})$ from the discrete solution $U_h = (U_{h_1}, \ldots, U_{h_p})$, with $e_{h_i} \equiv u_{h_i} - U_{h_i}$. By subtracting the above equations from the global discretization (7) we obtain

\[
\begin{align*}
L_{h_i}e_{h_i} &= \alpha_i, \quad \text{on } \Omega_{i,h_i}', \\
e_{h_i} &= 0, \quad \text{on } \Gamma_{i,h_i}, \\
e_{h_i} - P^i e_h &= \beta_i, \quad \text{on } \partial \Omega_{i,h_i}' \setminus \Gamma_{i,h_i}.
\end{align*}
\]

By applying the stability of the global scheme from Section 3 we obtain that

\[
\sum_{i=1}^{p} \| e_{h_i} \|_{\infty} \leq \left( 1 + \frac{\sigma}{1 - \delta_0} \right) \left( \sum_{i=1}^{p} K_i \| \alpha_i \|_{\infty} + \sum_{i=1}^{p} \| \beta_i \|_{\infty} \right)
\leq C \left( 1 + \frac{\sigma}{1 - \delta_0} \right) \left( \sum_{i=1}^{p} K_i h_i^{p_i} \| u \|_{p_i+1,\infty} \right) + \sum_{i=1}^{p} h_i^{q_i} \| u \|_{q_i+1,\infty}.
\]

This establishes the accuracy of the global scheme. □

**Remark 4.1.** We may alternatively use the largest of the maximum norms on the subgrids since

\[
\max_i \| e_{h_i} \|_{\infty} \leq \sum_{i=1}^{p} \| e_{h_i} \|_{\infty}.
\]

**Remark 4.2.** The parameters $C$, $\sigma$ and $\delta_0$ are independent of the ratios $h_i/h_j$ of the mesh sizes.

5. **Iterative methods for solving the global discretization.** In this section we discuss two iterative methods for solving the linear system corresponding to the global discretization (7). One is a Schwarz type iterative method and the other is a Krylov subspace iterative method with the additive Schwarz method as a preconditioner.

5.1. **A parallel Schwarz iterative method.** The iterative procedure we describe is a parallel variant of the Schwarz alternating method, see for instance [6, 10, 13, 14, 21, 26, 32] and involves solving problems on each of the subgrids $\Omega_{i,h_i}'$. We describe the iterative procedure using the contraction mapping $T$.

For $i = 1, \ldots, p$ compute $U_{h_i}^0$ as follows:

\[
\begin{align*}
L_{h_i}U_{h_i}^0 &= f_{h_i}, \quad \text{on } \Omega_{i,h_i}', \\
U_{h_i}^0 &= g_{h_i}, \quad \text{on } \Gamma_{i,h_i}, \\
U_{h_i}^0 &= 0, \quad \text{on } \partial \Omega_{i,h_i}' \setminus \Gamma_{i,h_i}.
\end{align*}
\]

Until convergence, for $\{n = 0, 1, \ldots \}$ do:

Compute $U_{h}^{n+1} = TU_{h}^n$, for $i = 1, \ldots, p$ in parallel, as follows:

\[
\begin{align*}
L_{h_i}U_{h_i}^{n+1} &= f_{h_i}, \quad \text{on } \Omega_{i,h_i}', \\
U_{h_i}^{n+1} &= g_{h_i}, \quad \text{on } \Gamma_{i,h_i}, \\
U_{h_i}^{n+1} &= T^i U_{h_i}^n, \quad \text{on } \partial \Omega_{i,h_i}' \setminus \Gamma_{i,h_i}.
\end{align*}
\]
Define $U_h^{n+1} = (U_{h_1}^{n+1}, \ldots, U_{h_p}^{n+1})$.

End do

The following theorem provides an estimate for the rate of convergence of $U_h^n$ to the exact discrete solution $U_h$.

**Theorem 5.1.** Let $\delta_0$ be the contraction factor of $T$. Then, the iterates $\{U_h^n\}$ converge geometrically to the exact discrete solution $U_h$. i.e.,

$$d(U_h^{n+1}, U_h) \leq \delta_0 d(U_h^n, U_h) \leq \delta_0^n d(U_h^0, U_h).$$

**Proof.** This is a standard result about contraction mappings, see for instance [3]. □

**Remark 5.1.** If the overlap $\theta$ between the domains $\Omega_i$ is sufficiently large, then, for $h_i$ sufficiently small, the contraction factor $\delta_0$ can be chosen uniformly less than 1, see [12, 25], and consequently, the convergence rate of the iterative procedure is uniform in the mesh parameters.

**Remark 5.2.** The dependence of the contraction factors $\rho_i$ on the overlap parameter $\theta$ and the lower bound $c_0$ is known, see for instance [24]. For sufficiently small $h_i$, the discrete contraction factors $\rho_i$ satisfy

$$\rho_i \leq e^{-\alpha \theta c_0},$$

where $\alpha > 0$ is independent of $c_0$ and $\theta$.

**5.2. An additive Schwarz preconditioned GMRES method.** The Schwarz iterative method introduced in the previous subsection does converge, but is generally slow, as one can see from the examples in Section 6.1 of this paper. It turns out a slight modification of the algorithm in Section 5.1 offers a very good preconditioner for any Krylov subspace type iterative methods, such as GMRES [30]. To define the additive Schwarz preconditioner, we let $A_i$ be the stiffness matrix corresponding to the discretization of

$$\begin{cases}
L_{h_i} U_{h_i}^0 &= f_{h_i}, \quad \text{on } \Omega_{i,h_i}^L \\
U_{h_i}^0 &= g_{h_i}, \quad \text{on } \Gamma_{i,h_i} \\
U_{h_i}^0 &= 0, \quad \text{on } \partial \Omega_{i,h_i} \setminus \Gamma_{i,h_i}.
\end{cases}$$

Note that zero Dirichlet boundary condition is used on all subdomain boundaries. We define

$$M^{-1} = diag(A_1^{-1}, A_2^{-1}, \ldots, A_p^{-1})$$

as a block diagonal matrix. Let

$$AU_h = F_h$$
be the matrix form of the global linear system (7). Then the additive Schwarz preconditioned GMRES reads as follows. Find the solution \( U_h \) by solving

\[
M^{-1}AU_h = M^{-1}F_h
\]

using GMRES.

We remark that this is a block diagonal preconditioner, and is fully parallel. In a parallel implementation, if the submeshes and the associated vectors are assigned to different processors, then the preconditioner is communication free. We also note that our maximum principle based theory is not applicable for analyzing the optimal convergence of the additive Schwarz preconditioned GMRES. Numerically, we do observe that when the overlap is fixed, the number of GMRES iterations is independent of the level of refinement. And for a fixed mesh, the number of iterations decreases as we increase the size of the overlap. Several numerical experiments with this method are reported in the next section.

6. Numerical results. In this section, we present some results of sample numerical tests involving non-matching, overlapping grids. The elliptic equation we consider is of the form

\[
\begin{aligned}
-\Delta u + cu &= f, & \text{in } \Omega, \\
u &= 0, & \text{on } \partial\Omega,
\end{aligned}
\]

where \( c \) is a constant given below. The domain \( \Omega \) is the union of some rectangular subdomains. On each of the rectangular subdomains, we use a uniform mesh as indicated in the tables. The local discretization is the standard 5-point finite difference scheme, which satisfies a discrete maximum principle and is stable in the maximum norm.

6.1. Two-subdomain case. We first exam the two subdomain cases. Let \( \Omega = [0, 2] \times [0, 1] \), and we consider a partition involving two subdomains with \( \Omega_1 = [0, 1] \times [0, 1] \), and \( \Omega_2 = [1, 2] \times [0, 1] \). The overlapping domains \( \Omega_1' \) and \( \Omega_2' \) are chosen as indicated in the tables. The forcing term \( f \) is chosen so that the exact solution is \( u(x, y) = (\sin(\pi x) + \sin(\frac{\pi}{2} x)) \sin(\pi y) \). For the interpolation maps \( I^1 \) and \( I^2 \), we use piecewise linear interpolations, and consequently we have

\[
\|I^1\|_{\infty} = 1, \quad \|I^2\|_{\infty} = 1.
\]

The global linear system is solved by the Schwarz alternating method introduced in Section 5, and the stopping criteria for the iteration is to reduce the maximum norm of the initial residual by a factor \( 10^{-12} \).

In our first test, we fix the overlapping parameter to be \( \theta = 0.45 \). The mesh size in subdomain 1, is chosen to be \( h_1 = 0.2 \times 2^{-l} \) and in subdomain 2, it is chosen to be \( h_2 = 0.25 \times 2^{-l} \), where \( l \) is the level of refinement to be given later. The resulting global grid is non-matching. In Table 1 below, we list the maximum norm of the global errors, and also list in brackets, the number of Schwarz iterations for the values of \( c \) listed. As predicted by the theory, since the overlap is fixed, the contraction factor \( \delta_0 \)
TABLE 1

Global error in the maximum norm when varying the level of refinement as \( h_1 = 0.2 \times 2^{-l}, \ h_2 = 0.25 \times 2^{-l} \). The number of Schwarz iterations is given in (\( \cdot \)). \( l \) is the level of refinement.

</table>

is independent of the mesh sizes \( h_i \). It can be easily verified that the global accuracy of the resulting scheme is of 2nd order, and the number of Schwarz iterations is bounded independent of the mesh sizes.

In our second test, we fix the mesh sizes in the subdomains to be \( h_1 = 0.2 \times 2^{-\gamma} \) and \( h_2 = 0.25 \times 2^{-\gamma} \). The overlapping parameter \( \theta \) varies as \( \theta = 0.45 \times 2^{-5\gamma} \) for some \( \gamma \) to be given in Table 2. Note that for \( \gamma = 32 = 2^5 \), we recover the overlap used in our previous tests. We tabulate the maximum norm of the global error for several values of \( c \). The number of Schwarz iterations is given in brackets. We note that as the overlap increases, the global accuracy increases, and the number of Schwarz iterations decreases. It can be shown that the contraction factor \( \delta_0 \) of the mapping \( T \) increases to 1 as the overlap decreases, see for instance [25]. Thus the results are consistent with the theory.

In both of the tests, we note that the error and the number of iterations do not depend strongly on the parameter \( c \) which was assumed to be positive in [25] for obtaining the desired theoretical bounds.

6.2. Many-subdomain case. We next run several tests for the cases of many subdomains. Let \( \Omega = (0,1) \times (0,1) \). We choose the forcing term \( f \) so that the exact

The solution is $u(x, y) = \sin(\pi x) \sin(\pi y)$. We first divide $\Omega$ into $k \times k$ equal subdomains in the checkerboard form, and each subdomain has its own mesh size $h_{i,j}$, $i, j = 1, \ldots, k$. The overlapping subdomains are obtained by extending each subdomain outward by ovlp layers of size $h_{i,j}$. Bilinear interpolations are used for all the subdomain boundaries. We shall restrict ourselves to the case $c = 0.0$. We solve the preconditioned system with GMRES and we stop the iteration when the initial preconditioned residual is reduced by a factor of $10^{-6}$. The subdomain problems are solved exactly with the sparse Gaussian elimination.

Table 3 summarizes the four subdomain case. The initial mesh contains four subgrids of sizes $6 \times 6$, $7 \times 7$, $8 \times 8$ and $9 \times 9$ and is refined 3 times. The order of accuracy, Order, is obtained by comparing the error with the error of the previous refinement level, as in row 4 of Table 3. $n$ is the total number of unknowns. ovlp denotes the number of elements in the overlapping domain. As the level of refinement increases, we increase ovlp so that the physical size of the overlap stays the same. Clearly, the order of accuracy is 2. The number of GMRES iterations is nearly independent of the refinement levels.

For the same 4 subdomain case, we fix the mesh sizes at the refinement level $l = 2$ and vary the overlap sizes. The results are given in Table 4. As one can see, better accuracy can be obtained by using larger overlap, though this accuracy will not improve beyond the accuracy of the local discretizations and interpolation maps. The number of GMRES iterations decreases as we increase the size of overlap.

We remark that it may be noted that when the local grids match, and the standard interpolation map is used (with zero error), the global discretization is equivalent to the standard discretization on the global matching grid. Consequently, increasing the overlap will not improve the global accuracy for matching grids.

We next consider a case when the solution has a much larger gradient in the center
of the domain, i.e., we set the exact solution of the problem to

\[ u(x, y) = 100 \sin(2\pi x) \sin(2\pi y) e^{-100((x-0.5)^2 + (y-0.5)^2)}. \]

Note that a finer mesh is needed in order to resolve the sharp front of the solution in the center of the domain. We compare the accuracy of the solution with two uniform meshes of sizes 128 \times 128 and 256 \times 256, with two non-matching overlapping meshes with nine subdomains whose mesh sizes are given in Table 5. In the non-matching grid case, we use a finer mesh in the center of the domain. As shown in Table 5, a nine subdomain mesh with a total of 3536 mesh points produces a comparably accurate solution as that of a uniform mesh with 16384 mesh points. A non-matching grid with 13465 points gives a more accurate solution than a uniform mesh with 65536 points. Both methods have better than 2nd order convergence for this particular test case.
